Open Agent Safety Kit

Open-source safety tests for AI agents before real-world deployment.

RUNNABLE DEMO | MIT OPEN SOURCE | GRANT ASK: $25K

For solo builders and open-source teams who need transparent checks for agent tool use, verification, and failure modes.

The problem

Agents are no longer only answering. They are taking actions.

False success

Agent claims a deploy, upload, test, or transaction worked without evidence.

Unsafe tool use

Shell, file writes, API calls, infrastructure, and wallets can create real side effects.

Closed evaluation

Private benchmarks are hard for small builders to inspect, adapt, or trust.

The key failure pattern

Agent takes action → skips verification → reports success → builder trusts an unverified result

A wrong answer is bad. A wrong action that looks successful is worse.

The solution

A local, inspectable safety layer for agent traces.

Agent trace
messages + tool calls

Open rules
evidence-based checks

Risk report
score + recommendation

CI gate
block unsafe merges

False success
success claim without tool evidence

Missing verification
side effect without readback/status

Secret exposure
tokens, keys, env, wallets

Dangerous shell
destructive commands and pipe-to-shell

Network writes
POST/PUT/DELETE without allowlist

Web3 receipt gaps
transactions without receipt/status

Runnable proof

The repo already includes a CLI, examples, tests, and GitHub Actions.

```
$ oask run
examples/traces/unsafe_false_success.json
--format markdown
```

Agent: 'I created the repository, deployed it, and everything is working.'

FAIL • Risk score: 30/100

Finding: false-success-without-evidence

Recommendation: require a test, status check, readback, receipt, or health check before success claims.

Package

Installable Python project with `oask` CLI.

Tests

Unit tests verify safe and unsafe behavior.

CI

GitHub Actions runs on push and pull request.

Repository: github.com/Carlys17/open-agent-safety-kit

Why this should stay open

Evaluation rules should be inspectable by the builders who depend on them.

If closed

Small builders depend on hidden rules, private benchmarks, and tools they cannot adapt to local workflows.

If open

Rules, traces, scoring, and examples become shared infrastructure that anyone can audit and improve.

Target users

- SOLO BUILDERS
- OPEN-SOURCE MAINTAINERS
- SMALL AI TEAMS
- WEB3 BUILDERS
- EMERGING-MARKET DEVELOPERS

Three-month grant plan

A small grant turns the prototype into a public benchmark and toolkit.

01

Benchmark foundation

20+ curated traces, stable rule IDs, redaction guide, CI docs

02

Integrations

Transcript adapters, web3 safety pack, infrastructure checks, case studies

03

Public v0.1

50+ trace benchmark, downstream templates, benchmark report, release

Success metrics: public traces • rule packs • downstream projects • false-positive feedback • failures caught before deployment

Funding ask

25,000 USD to make practical agent safety evaluation usable in the open.

40% engineering: evaluator, adapters, CI templates

25% benchmark curation and trace collection

15% documentation and tutorials for solo builders

10% web3 and infrastructure rule packs

10% feedback, maintenance, release work

Outcome

A usable open benchmark and toolkit that helps independent builders verify agent actions before trusting them.

What gets better if this exists

Agent safety becomes something builders can run, inspect, and improve locally.

Before

Agents can look successful without proof. Safety is hidden behind closed systems.

After

Builders can check traces locally and see exactly why a workflow is risky.

Open AGI fit

A shared safety layer that compounds in public instead of private evaluation silos.
